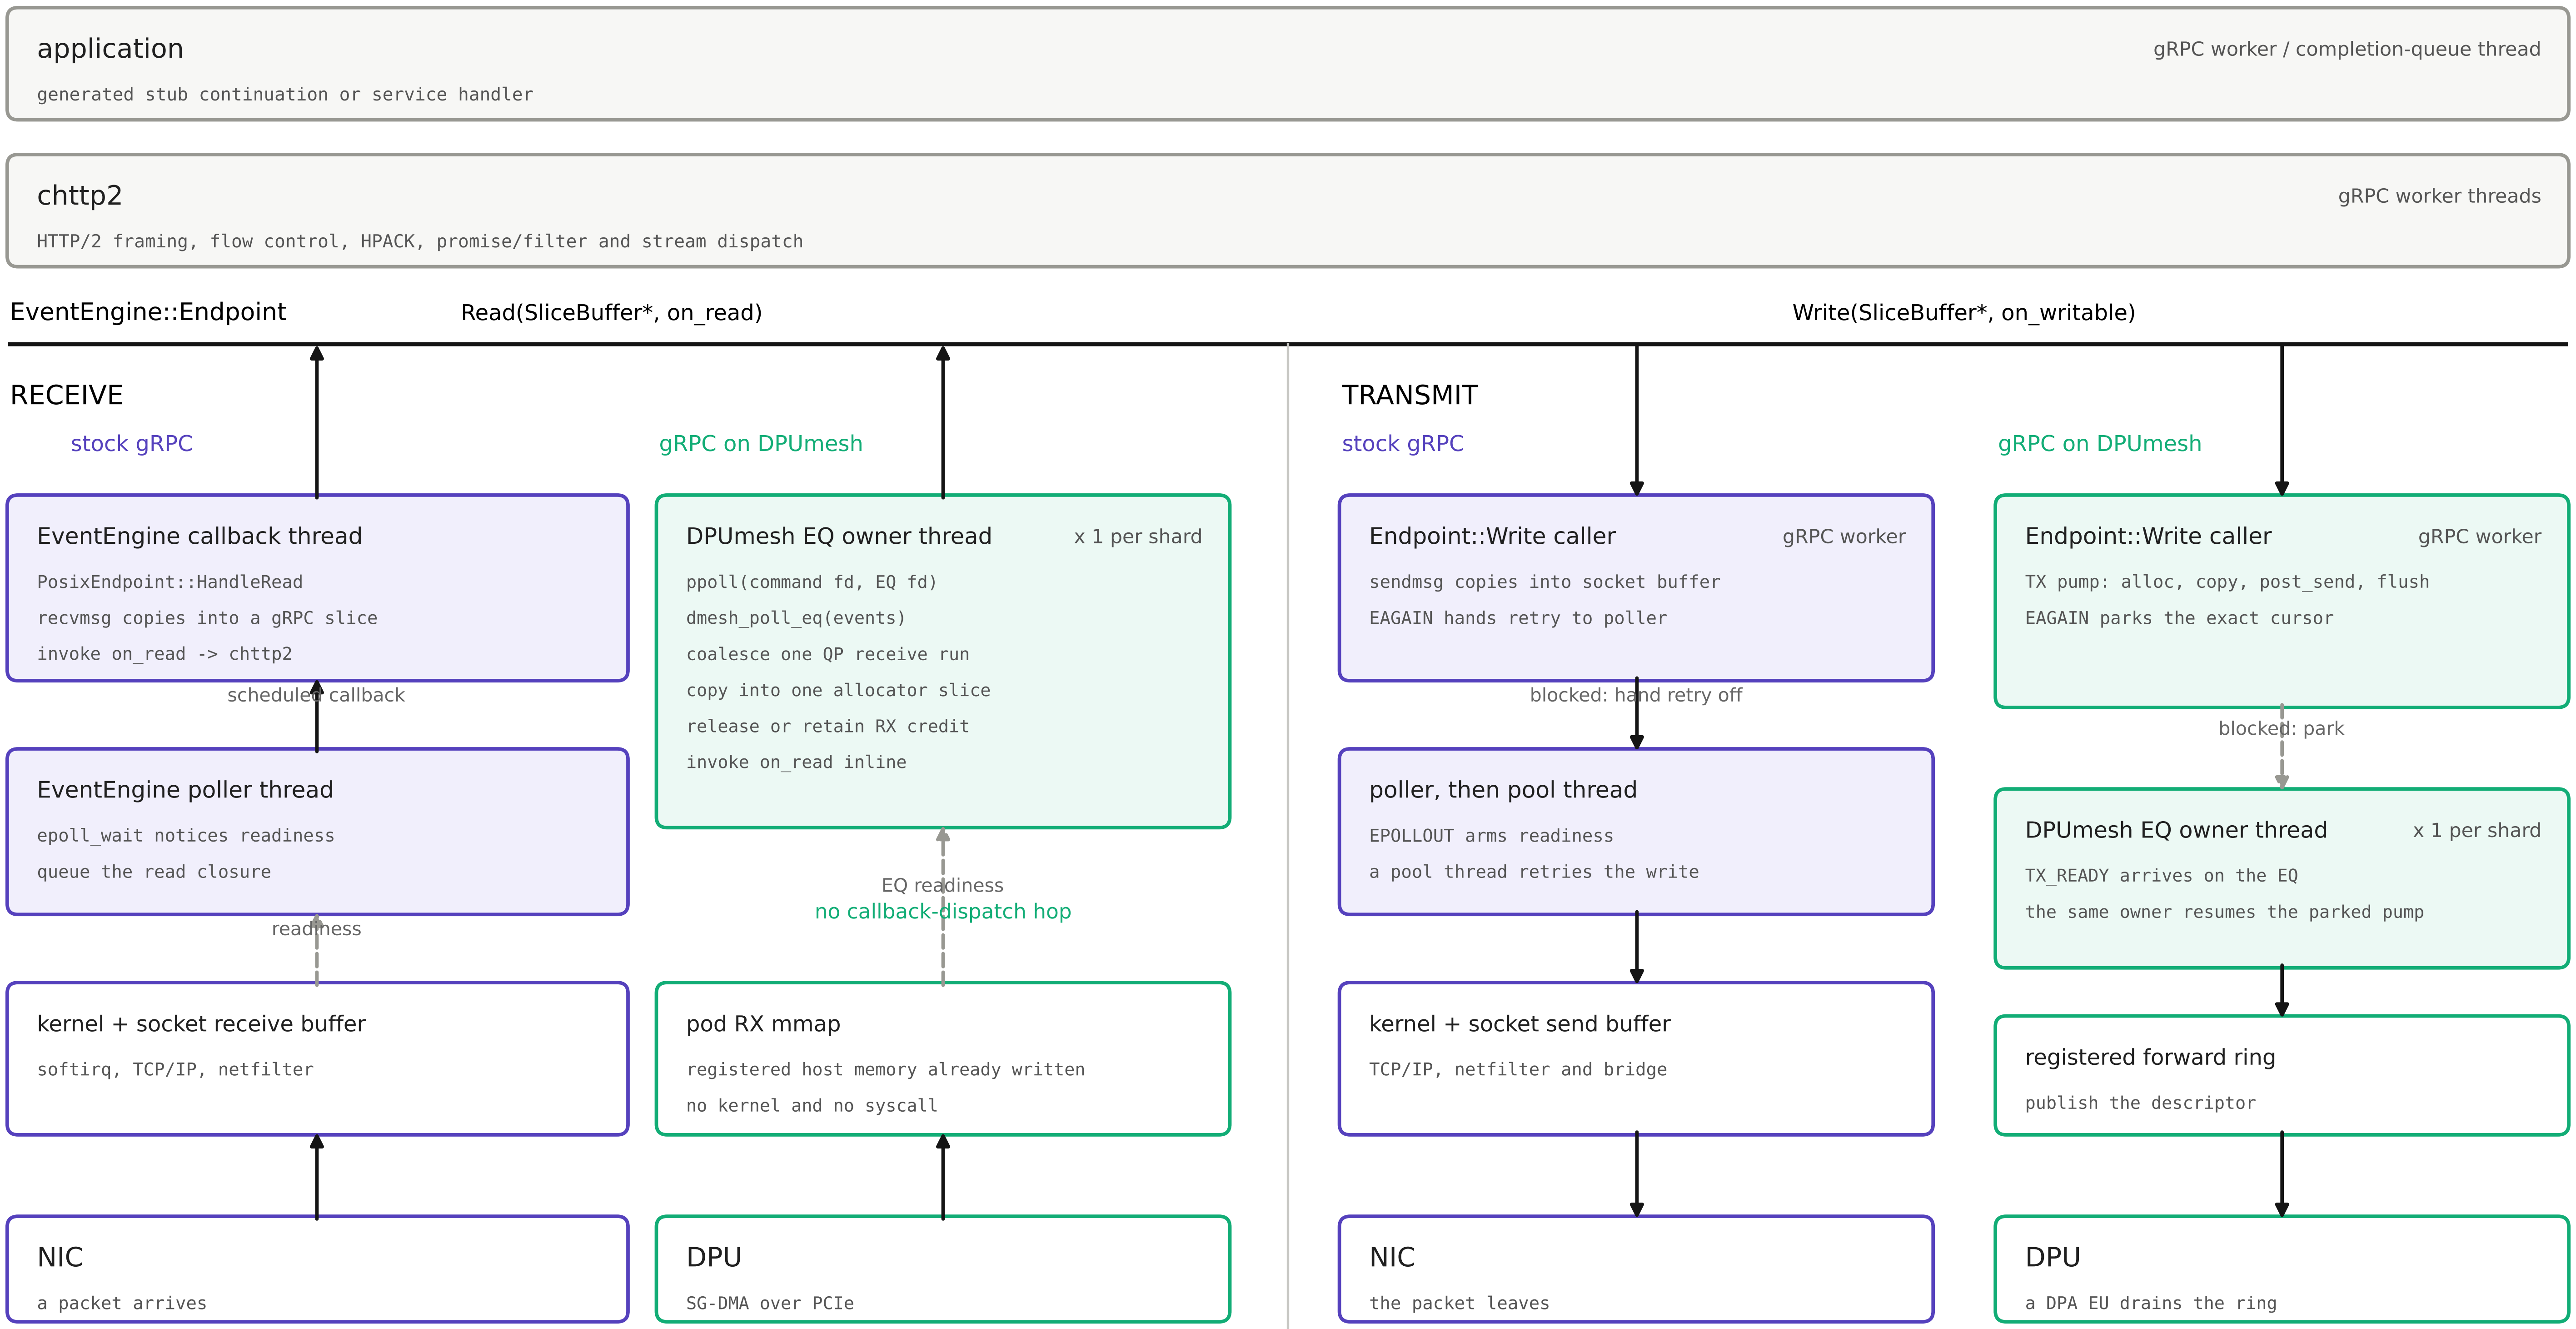
Where DPUmesh enters gRPC — both directions

Everything above the seam is stock gRPC. DPUmesh replaces only the transport below it.



what actually changed

RX: one EQ owner reaches chttp2 directly after the DPU has DMA'd bytes into registered memory.
TX: the caller pumps immediately; TX_READY returns to that QP's EQ owner without a pool hand-off.
The callback dispatcher is a separate control/terminal path, not an extra normal-data-path hop.

How to read this figure

EventEngine	gRPC's transport interface; an Endpoint is one byte stream	EQ owner thread	the adapter's reactor shard: one thread per event queue
chttp2	gRPC's own HTTP/2 implementation, unchanged here	TX_READY	event saying a blocked stream may retry its send
QP	one full-duplex DPUmesh byte stream behind one Endpoint	pod RX mmap	registered host memory the DPU writes received bytes into
